Main References

A **Metric Measure Space** (or MM space) is a set $X$ equipped with a metric $d$ and a positive Borel measure $\mu$ that is doubling; $\exists C$ positive such that

$$\mu(B_d(x, 2r)) \leq C \mu(B_d(x, r)).$$
Given a metric, there is always a measure that we can construct on the space:

**Hausdorff Measure**

For any $s$ nonnegative, $A \subset X$, define the $s$-dimensional Hausdorff outer measure:

$$H^s(A) = \lim_{\delta \to 0} H^s_\delta = \lim_{\delta \to 0} \inf \left\{ \sum_{j=1}^{\infty} (\text{diam} E_j)^s : A \subset \bigcup_{j=1}^{\infty} E_j, \text{diam} E_j < \delta \right\}.$$

A set $A$ has **Hausdorff dimension** $D_H$ if

$$D_H = \inf\{s \geq 0 : H^s(A) = 0\} = \sup\{s \geq 0 : H^s(A) = \infty\}.$$

We call $H^D$ the **D-dimensional Hausdorff measure** when restricted to Borel sets.
An example of the $s$-dimensional Hausdorff measure of a set $A$ with Hausdorff dimension $D_H$. 
MM spaces are a growing area of research, especially in fields such as:

- Harmonic Analysis
- Partial Differential Equations
- Probability Theory
- Function Spaces
- Geometric Analysis on Non-Smooth Spaces
- Analysis on Fractals
We will see that we need a stronger requirement than just the doubling condition:

**Ahlfors regularity**

A MM space is **Ahlfors regular of dimension** $D$ (here on, regular) if there exists $K > 0$ such that

$$K^{-1} r^D \leq \mu(B(x, r)) \leq K r^D$$

for all $x \in X$, $0 < r \leq \text{diam} X$.

If only the upper (resp. lower) bounds are satisfied, we call the space **upper (resp. lower) Ahlfors regular of dimension** $D$. 
The measure $\mu$ of a regular $D$ dimensional space and $H^D$ are equivalent in that there is a constant $C$ depending only on $K$ such that

$$C^{-1}\mu(E) \leq H^D(E) \leq C\mu(E) \quad \forall \text{ Borel } E \subseteq X.$$ 

In particular, if the MM space triple $(X, d, \mu)$ is regular of dimension $D$, then so is $(X, d, H^D)$. 
Symbolic Cantor sets

Let $F$ be a finite set with $k \geq 2$ elements. Then $F^\infty = \{\{x_i\}_{i=1}^\infty : x_i \in F\}$ is the $k$-Cantor set.

Define the valuation $L(x, y)$, $x = \{x_i\}_{i=1}^\infty$, $y = \{y_i\}_{i=1}^\infty$, by

$$L(x, y) = \ell,$$

where $x_i = y_i$ $\forall i \leq \ell$, $x_{\ell+1} \neq y_{\ell+1}$. 
Symbolic Cantor sets

Let \( a \in (0, 1) \). Then

\[
d_a(x, y) = a^{L(x,y)}
\]
is an ultrametric.

Place the natural probability measure \( \mu = \prod_{i=1}^{\infty} \nu, \quad \nu(j) = 1/k \) for \( j \in F \).

Then \( F^\infty \) is regular of dimension \( D = \frac{\log k}{\log a^{-1}} \).
Symbolic Cantor sets

The Cantor set is generated by successive removals of middle thirds.
Laakso graph

Let $X_0 = [0, 1]$. For $i > 0$, define $X_i$ by replacing each edge of $X_{i-1}$ by a $4^{-(i-1)}$ scaled copy of $\Gamma$ (below). Then $\{X_i\}_{i=0}^\infty$ forms an inverse system

$$X_0 \leftarrow \ldots \leftarrow X_i \leftarrow \ldots,$$

where $\pi_{i-1} : X_i \rightarrow X_{i-1}$ collapses the copies of $\Gamma$ at the $i$-th level.

Graph of $\Gamma$
Then the inverse limit $X_\infty$ is the **Laakso graph**, with metric

$$d_\infty(x, x') = \lim_{i \to \infty} d_{X_i}(\pi_i^\infty(x), \pi_i^\infty(x')),$$

where $X_\infty$ is the Gromov-Hausdorff limit of $\{X_i\}$ and $\pi_i^\infty : X_\infty \to X_i$ is the canonical projection.

The Laakso graph is a compact, and hence complete, metric space. This guarantees the existence of a doubling measure that makes the Laakso graph an MM space.

Of similar construction is the **Laakso space**, which is regular of dimension

$$D = 1 + \frac{\log 2}{\log 3}.$$
Heisenberg Group

We define the **n-dimensional Heisenberg group** in its algebra representation $\mathbb{H}^n = \mathbb{C}^n \times \mathbb{R}$ with group multiplication given by

$$(z, t)(z', t') = (z + z', t + t' - \frac{1}{2}\text{Im} \sum_{j=1}^{n} z_j z_j^*)$$

There is a natural dilation action $\partial_r(z, t) = (rz, r^2 t)$, $r > 0$, that gives rise to the homogeneous norm $\|(z, t)\| = (\sum_{j=1}^{n} |z_j|^4 + t^2)^{\frac{1}{4}}$, with the properties $\|\partial_r(z, t)\| = r\|(z, t)\|$ and $\|x^{-1}\| = \|x\|$. 

Sean Watson (UCR)  
Complex Dimensions in MM Spaces
This norm defines a metric $d(x, y) = \|x^{-1}y\|$.

The Haar measure given by Lebesgue measure under the exponential map gives

$$\mu(B(x, r)) = r^{2n+2}\mu(B(x, 1)).$$

Thus the Heisenberg group is regular of dimension $D = 2n + 2$, while its topological dimension is $T = 2n + 1$. 
Many self-similar fractals in Euclidean space can be thought of as MM or Ahlfors regular spaces.

Using key work of Kusuoka, Kigami showed that the Sierpiński gasket could be embedded in $\mathbb{R}^2$ by a certain harmonic map. He also showed the resulting harmonic Sierpiński gasket can be viewed as a measurable Riemannian manifold with the intrinsic geodesic metric induced by the Euclidean structure of $\mathbb{R}^2$.

More recently, Kajino proved that the harmonic gasket is an Ahlfors regular space under the associated Hausdorff measure.
Sierpiński Gasket
We define **weighted** $\mathbb{R}^N$ space as the triple $(\mathbb{R}^N, d, \mu)$, where $d$ is the standard Euclidean metric and $\mu$ is the measure defined as

$$d\mu = |x|^\alpha dx, \quad \alpha > -N,$$

with $dx$ being the Lebesgue measure.

Then weighted $\mathbb{R}^N$ space is a MM space, but it is not Ahlfors regular.
What defines a fractal?

Two dimensions that capture how volume scales under dilations or contractions: the Hausdorff dimension and the Minkowski dimension.

**Minkowski dimension**

Given $A \subset \mathbb{R}^N$ bounded, define the *t-neighborhood of $A$* by $A_t := \{x \in \mathbb{R}^N : d(x, A) < t\}$. Then the *r-dimensional Minkowski upper content* is defined as

$$M^r = \limsup_{t \rightarrow 0} \frac{|A_t|}{t^{N-r}}.$$

Define the *upper Minkowski dimension* by

$$\overline{\dim}_B A = \inf\{r \in \mathbb{R} : M^r(A) = 0\} = \sup\{r \in \mathbb{R} : M^r(A) = \infty\}.$$
What defines a fractal?

An example of the $r$-dimensional Minkowski upper content of a set $A$ with Minkowski dimension $\dim_B A$. 
What defines a fractal?

We define the \textbf{r-dimensional lower Minkowski content} $M_r^*$ and \textbf{lower Minkowski dimension} $\dim_B(A)$ analogously.

\textbf{Minkowski dimension cont.}

Given a set $A \subset \mathbb{R}$, if

$$\underline{\dim}_B A = \overline{\dim}_B A,$$

then we call their common value $\dim_B A$ the \textbf{Minkowski dimension} of $A$.

However, it is not enough to say that non-integer scaling dimensions or scaling dimensions larger than topological dimension defines a fractal.
What defines a fractal?

The Devil’s staircase, which has Minkowski, Hausdorff and topological dimensions $D = 1$. 
What defines a fractal?

However, as done in [FGCD], we find that by studying the volume of the $\epsilon$-neighborhoods of the Devil’s staircase, it is approximated by

$$ V(\epsilon) \approx 2\epsilon^{2-1} + \frac{4 - \pi}{8 \log 3} \sum_{n=-\infty}^{\infty} \frac{\epsilon^{2-D-inp}}{(D + inp)(1 - D - inp)}, $$

where $D = \log_3 2$ and $p = 2\pi / \log 3$.

Viewing the exponents of $\epsilon$ as codimensions, we see that the dimensions associated to the geometry of the Devil’s staircase are 1 and $D + inp$ for any $n \in \mathbb{Z}$. In particular, there are complex values associated to these dimensions. We call the entire set of dimensions the complex dimensions of the Devil’s staircase.
What defines a fractal?

The complex dimensions of the Devil’s staircase, with $D = \log_3 2$ and $p = 2\pi / \log 3$. 
The theory of complex dimensions in $\mathbb{R}$ was developed through the use of fractal strings (one-dimensional fractal drums) in [FGCD].

**Fractal String**

A **fractal string** is a bounded open subset of the real line; i.e. it is a disjoint union of open intervals (the boundary of which may be fractal). The lengths of these open intervals forms a non-increasing sequence

$$\mathcal{L} = \ell_1, \ell_2, \ell_3, \ldots$$

For example, we define the **Cantor string**, $\text{CS}$, as the complement of the ternary Cantor set in $[0, 1]$. Thus in terms of the lengths of the disjoint open intervals,

$$\text{CS} = \left\{ \frac{1}{3}, \frac{1}{9}, \frac{1}{27}, \frac{1}{27}, \frac{1}{27}, \frac{1}{27}, \ldots \right\}$$
The Cantor string represented as a fractal harp.
Geometric Zeta Function

Given a fractal string $L$, we define its complex valued geometric zeta function, $\zeta_L$ as

$$\zeta_L(s) = \sum_{j=1}^{\infty} \ell_j^s.$$ 

This function is holomorphic on $\text{Re } s > D =$ Minkowski dimension of $\partial L$. Moreover, this half-plane is optimal in the sense that $D$ is the abscissa of absolute convergence of $\zeta_L$.

We define the complex dimensions as the poles of the meromorphic continuation.
Thus, the Cantor String has geometric zeta function
\[ \zeta_{CS}(s) = \sum_{n=1}^{\infty} \frac{2^{n-1}}{3^{ns}}. \]

This is absolutely convergent and holomorphic for \( \text{Re } s > \log_3 2 = D \). It has a meromorphic continuation to all of \( \mathbb{C} \) given by
\[ \zeta_{CS}(s) = \frac{1}{3^s} \cdot \frac{1}{1 - 2 \cdot 3^{-s}}, \]

with complex dimensions equal to the set of poles
\[ \left\{ D + in \frac{2\pi}{\log 3} : n \in \mathbb{Z} \right\}. \]
The complex dimensions of the ternary Cantor set, with $D = \log_3 2$ and $p = 2\pi / \log 3$. 
We find that the Cantor String tube formula (volume of the inner \( \epsilon \)-tube) is

\[
V_{CS}(\epsilon) = \frac{1}{2 \log 3} \sum_{n=-\infty}^{\infty} \frac{(2\epsilon)^{(1-D-inp)}}{(D + inp)(1 - D - inp)} - 2\epsilon
\]

where \( p = 2\pi / \log 3 \) and \( \frac{1}{2 \log 3} \) is the residue of \( \zeta_{CS} \) at each of the poles.
Spectrum and Riemann Hypothesis

Given a Minkowski measurable fractal string $\mathcal{L}$, its frequency (spectral) counting function $N_{\nu,\mathcal{L}}(\mu)$ admits a monotonic asymptotic second term of the form $-c_D \mathcal{M} \mu^{D/2}$, where $D \in (0, 1)$.

The constant $c_D$ depends only on $D$ and is directly proportional to $-\zeta(D)$, the Riemann zeta function.

This result was obtained by Lapidus and Pomerance, thereby establishing a connection between the direct spectral problem, Minkowski measurability, and the Riemann zeta function.
Fractal Strings

Inverse Spectral Problem

Given that \( L \) is a fractal string for which the spectral counting function \( N_{\nu,L}(\mu) \) admits a monotonic asymptotic second term proportional to \( \mu^{D/2} \) (as \( \mu \to \infty \)), does it follow that \( L \) is Minkowski measurable?

It has been shown by Lapidus and Maier that the inverse spectral problem is intimately connected with the location of the critical zeros of \( \zeta(s) \).

Theorem [LaMa]

The inverse spectral problem has an affirmative answer for all \( D \in (0,1) \), with \( D \neq 1/2 \), if and only if the Riemann hypothesis is true.
In order to generalize the theory to \( \mathbb{R}^N \), the distance zeta function was introduced in [FZF].

**Distance Zeta Function**

Given a bounded set \( A \subset \mathbb{R}^N \), \( \delta > 0 \), we define the **distance zeta function** as

\[
\zeta_A(s) = \int_{A_\delta} d(x, A)^{s-N} dx,
\]

for \( s \in \mathbb{C} \) with \( \text{Re} \ s \) sufficiently large, and the integral taken in the Lebesgue sense.

It will turn out that for the properties of this function we wish to study, the value of \( \delta \) will not matter.
Distance Zeta Function

**Theorem [FZF]**

Given a bounded set \( A \subset \mathbb{R}^N \), \( \delta > 0 \), we define the distance zeta function

\[
\zeta_A(s) = \int_{A_\delta} d(x, A)^{s-N} \, dx.
\]

Then \( \zeta_A \) is holomorphic in the half-plane \( \{ \text{Re } s > \operatorname{dim} B(A) \} \) with

\[
\zeta_A'(s) = \int_{A_\delta} d(x, A)^{s-N} \log d(x, A) \, d\mu.
\]

We have that \( \operatorname{dim} B(A) \) is optimal, in the sense that it is the abscissa of Lebesgue convergence of \( \zeta_A \).

Further, if \( D = \operatorname{dim} B(A) \) exists and \( \mathcal{M}_*^D > 0 \), then \( \zeta_A(s) \to +\infty \) as \( s \in \mathbb{R} \) converges to \( D \) from the right.
If $\zeta_A$ can be meromorphically extended, then we call the poles of such an extension the **complex dimensions** of the set $A$.

As we shall see, these poles will differ slightly compared to the geometric zeta function for fractal strings. It is currently unknown if this is perhaps due to the geometric realization of the fractal strings used.

However, the **principal complex dimensions**, the poles above the critical line $\{\text{Re } s = D\}$ where $D$ is the abscissa of holomorphic convergence, will coincide.
Given any nontrivial fractal string, \( \mathcal{L} \), define \( A := \{a_k : k \geq 1\} \), where
\[
a_k := \sum_{j \geq k} l_j.
\]
Then we have that
\[
\zeta_A(s) = u(s)\zeta_\mathcal{L}(s) + v(s)
\]
where \( u, v \) are both holomorphic functions in the right half-plane
\( \{s \in \mathbb{C} : \Re s > 0\} \).

Further, the set of poles of the meromorphic extensions of \( \zeta_A \) and \( \zeta_\mathcal{L} \) coincide to the right of any open half-plane \( \{\Re s > c\} \) for \( c > 0 \).
In particular, the complex dimensions coincide to the right of \( \{\Re s = 0\} \).
The distance zeta function can be written in the following way: for any \( \text{Re } s > \dim_B(A) \),

\[
\int_{A_\delta} d(x, A)^{s-N} dx = \delta^{s-N}|A_\delta| + (N - s) \int_0^\delta t^{s-N-1}|A_t|dt.
\]

**Tube Zeta Function**

Let \( \delta > 0 \), \( A \) a bounded set in \( \mathbb{R}^N \). Then the **tube zeta function** of \( A \), \( \tilde{\zeta}_A \), is defined as

\[
\tilde{\zeta}_A(s) = \int_0^\delta t^{s-N-1}|A_t|dt
\]
Provided that $\dim_B(A) < N$, $\tilde{\zeta}_A$ shares important properties with $\zeta_A$.

**Theorem [FZF]**

Assume $A$ is a bounded subset of $\mathbb{R}^N$ with $\dim_B(A) < N$. Then $\tilde{\zeta}_A$ is holomorphic in the half-plane $\{\text{Re } s > \dim_B(A)\}$, where $\dim_B(A)$ is the abscissa of Lebesgue convergence.

Moreover, $\tilde{\zeta}_A$ and $\zeta_A$ will share the same domain of meromorphic extension (if it exists) with the same poles and order.

In particular, the complex dimensions are the same.
Theorem [FZF]

Assume that the bounded set \( A \subset \mathbb{R}^N \) is Minkowski nondegenerate (that is, \( \dim_B A = D \) and \( 0 < \mathcal{M}^*_D(A) \leq \mathcal{M}^*_D(A) < \infty \),) and \( D < N \). If \( \zeta_A(s) \) can be meromorphically extended to a neighborhood of \( s = D \), then \( D \) is necessarily a simple pole of \( \zeta_A(s) \) and

\[
(N - D)\mathcal{M}_*(A) \leq \text{res}(\zeta_A(\cdot), D) = (N - D)\text{res}(\tilde{\zeta}_A(\cdot), D) \leq (N - D)\mathcal{M}^*_D(A).
\]
Let $A$ be the ternary Cantor set, and let $\delta \geq 1/6$. Then we obtain

$$
\zeta_A(s) = 2^{1-s} s^{-1} \frac{3^{-s}}{1 - 2 \cdot 3^{-s}} + 2\delta^s s^{-1}
$$

Its residue at $D(A) = \log_3 2$ is equal to

$$
\text{res}(\zeta_A(\cdot), D(A)) = \frac{2}{\log 2} \left(\frac{1}{6}\right)^{\log_3 2-1} = \frac{1}{2^{\log_3^2} \log 2},
$$

while its upper and lower Minkowski contents are given by

$$
M^*_{\log_3 2}(A) = \frac{\log 9}{\log 3/2} \left(\frac{\log 3/2}{\log 4}\right)^{\log_3 2}, \quad M^*_{\log_3 2}(A) = 2^{2-\log_3 2}.
$$
More generally, at each of the poles on the critical line \( \{ \text{Res} = \log_3 2 \} \),
\[ s_k := \log_3 2 + kp i, \quad k \in \mathbb{Z}, \text{with} \quad p := \frac{2\pi}{\log 3}, \text{we have} \]
\[
\text{res}(\zeta_A(\cdot), s_k) = \frac{\log_3 2}{s_k 2^k p i} \text{res}(\zeta_A(\cdot), D(A)).
\]

In particular, it is noteworthy that these residues tend to zero as \( k \to \pm \infty \).
Sierpiński carpet

In parallel to the fractal string case, we will call $V(t) := |A_t|$ the volume of the $t$-tube neighborhood.

Let $A$ be the standard Sierpiński carpet in the plane. Then

$$|A_t| = t^{2-D}(G(\log t^{-1}) + O(t^{D-1}))$$

as $t \to 0$, where $D = \log_3 8$ and $G$ is a nonconstant periodic function with period $T = \log 3$.

By direct computation we can find that both zeta functions have a meromorphic extension to all of $\mathbb{C}$, and the set of complex dimensions of $A$ are simple poles given by

$$\text{dim}_\mathbb{C} A = \left\{ D + \frac{2\pi}{\log 3} ki : k \in \mathbb{Z} \right\}.$$
Sierpiński carpet
The complex dimensions of the Sierpiński carpet, with $D = \log_3 8$ and $p = 2\pi / \log 3$. 
Let $B_R(0)$ be the open ball in $\mathbb{R}^n$ with radius $R$, and let $A = \partial B_R(0)$ be the $(N - 1)$-dimensional sphere with radius $R$. Further, let $c_k = 1 - (-1)^k$ and $\omega_N = |B_1(0)|$.

Fix $\delta < R$. Then $\tilde{\zeta}_A(s)$ meromorphically extends to all $\mathbb{C}$, with representation

$$
\tilde{\zeta}_A(s) = \omega_N \sum_{k=0}^{N} c_k R^{n-k} \binom{N}{k} \frac{\delta^{s-N+k}}{s-(N-k)}.
$$

As expected, we get $D(A) = N - 1$, although (perhaps surprisingly) its set of complex dimensions is

$$
\dim_{\mathbb{C}}(A) = \left\{ N - 1, N - 3, \ldots, N - (2 \left\lfloor \frac{N-1}{2} \right\rfloor + 1) \right\}.
$$
The introduction of complex dimensions has led to a conjectured definition of fractality, first in [FGCD] and then further extended in [FZF], that would not leave out exceptional cases:

**Definition**

A geometric object is said to be a **fractal subset of** $\mathbb{R}^N$ if its associated fractal zeta function has at least one nonreal complex dimension.

This would include not only classical fractals, but former exceptions such as the Devil’s staircase.
Generalized Minkowski Dimension

Minkowski Dimension in MM spaces

Let $X$ be an Ahlfors regular MM space of dimension $D_H$. Then we define the \textit{r-dimensional upper Minkowski content} by

$$M^*_r = \limsup_{t \to 0} t^{D_H-r} \left| A_t \right|.$$ 

Lower content and Minkowski dimension are then defined analogously to the Euclidean case.

Ahlfors regularity is necessary to insure that the "ambient space" has consistent dimension, or generally that single points have Minkowski dimension 0. See weighted $\mathbb{R}^N$ space at $A = \{0\}$ for a counterexample.
Theorem (Lapidus, W.)

If we define $D(A) = \dim_B A$, then the distance zeta function,

$$\zeta_A(s) = \int_{A_\delta} d(x, A)^{s-DH} d\mu,$$

is holomorphic in the half plane $\{\text{Re } s > D(A)\}$, with

$$\zeta'_A(s) = \int_{A_\delta} d(x, A)^{s-DH} \log d(x, A) d\mu.$$

We have that $D(A)$ is optimal, in the sense that it is the abscissa of Lebesgue convergence of $\zeta_A$.

Further, if $D = \dim_B(A)$ exists and $\mathcal{M}^D_* > 0$, then $\zeta_A(s) \to +\infty$ as $s \in \mathbb{R}$ converges to $D$ from the right.
Future Work

- Is the analogous tube zeta function well defined and do further results involving these fractal zeta functions (relative fractal zeta functions, spectrums, etc.) generalize to MM spaces?

- Find and study examples of fractal sets (sets with nonreal complex dimensions) in MM spaces.

- Examine what information the complex dimensions give concerning the geometry of such fractal sets, in analogy to the Euclidean case.
