Sometimes the universal coefficients thm lets us go from these cases to coefficient ring Z .

Notation:(**anachronistic**) Let the coefficient ring k be \mathbb{Q} in the case of toral $((S^1)^n)$ actions and Z_p in the case of Z_p tori $(\oplus(Z_p))$.

Wu-Yi Hsiang Reformulation: (\sim ' 70) Organized around the philosophy that (for the above coeff. in the above grp cases) the free part of the equivariant cohomology goes most of the way towards determining the cohomology of the fixed point set. The torsion goes towards determining the orbit structure.

Wu-Yi Hsiang Reformulation: (\sim ' 70) Organized around the philosophy that (for the above coeff. in the above grp cases) the free part of the equivariant cohomology goes most of the way towards determining the cohomology of the fixed point set. The torsion goes towards determining the orbit structure. For non-abelian Lie groups G this doesn't work. The Hsiangs already showed given any finite complex K , there is a compact finite dimensional acyclic G -space X on which G acts with fixed point set $X^G = K$,

Lowell Jones (Annals of Math '71) and Bob Oliver's work (Comm. Math. Helv '75) solidified this idea further.

$$BS^1 = CP^\infty, B(Z_2) = RP^\infty.$$

So for G a torus or Z_2 -tori,

$$H^*(BG) = k[t_1, \dots, t_r]$$

where $\deg t_i$ is 2 or 1 respectively.

For p odd,

$$H^*(BG) = k[t_1, \dots, t_r] \otimes \wedge[\nu_1, \dots, \nu_r]$$

where $\deg(t_i) = 2$ and $\deg(\nu_i) = 1$.

In all these toral cases, for a (possibly p) torus of rank r , we use the notation

$$R := k[t_1, \dots, t_r]$$

for the polynomial part of the coefficient ring of equivariant cohomology H_G^* and R_0 for its field of fractions.

Thus a weight of a linear representation as a representation $w : G \rightarrow S^1$ is equally well viewed as a 2 dimensional cohomology class representing the pullback to BG of the generator in dim 2 of $H^*(CP^\infty)$. Also interpretable via transgression in the spectral sequence for $G \rightarrow EG \rightarrow BG$. Similarly in the p odd case of Z_p , weights are 2 dimensional cohomology classes and in the Z_2 case 1 dimensional cohomology classes.

Sps. X is a cohomology sphere with k coefficients.

The E_2 term of the spectral sequence for $X \rightarrow X_G \rightarrow BG$ is then $R \otimes H^*(X)$.

Let x and 1 be the lifts of the generators of $H^*(X)$ to $H^*(X_G)$.

When $F \neq \phi$,

$$H_G^*(X) \otimes_R R_0 \cong R_0[x]/(f(x))$$

This is the original Smith theorem.

When $F \neq \phi$,

$$H_G^*(X) \otimes_R R_0 \cong R_0[x]/(f(x))$$

Note it is really the multiplicative structure of the cohomology ring which distinguishes examples.

Linear models: Linear representations of $G = Z_2$ into $GL(N)$ are indexed by the number l of -1 's. The two canonical bundles over $X = G_2(R^N)$ are equivariant with respect to such an action, so for a linear action, the spectral sequence of $X \rightarrow X_G \rightarrow BG$ collapses. Hence for a linear action

$$H^*(X_G) = R[h_1, h_2]/(f^{N-1}, f^N)$$

and it is not hard to show that

$$f^{N-k} = \sum_{j=0}^{N-k} \rho_j h_{N-k-j}$$

where ρ_j is the j 'th elementary symmetric function of the weights (counting multiplicities) of the Z_2 representation.

For a general involution, consider the Serre spectral sequence for $X \rightarrow X_G \rightarrow BG$.

Prop:

- If N is even and not congruent to 64 mod 192, then the action of $\pi_1(BG)$ on $H^*(X, \mathbb{Z}_2)$ is trivial.
- For N even, if there is a nonempty fixed point set, then the spectral sequence collapses at the E_2 level.

Thus under the above dimension restrictions, for any involution, if $F \neq \phi$, we have fairly quickly shown that

$$H_G^*(X) = \mathbb{Z}_2[h_1, h_2, x]/(f, g)$$

where $f = h_{N-1} \pmod{x}$ and $g = h_N \pmod{x}$.

There is a nice part of the Steenrod algebra argument that works generically and only takes perhaps 20 pages to write down.

It is based on showing that a certain mod 2 binomial coefficient is *usually* nonzero.

Unfortunately, that coefficient does sometimes vanish, so there are a lot of special cases that had to be checked to give the full theorem.

Probably this example is one of the most computationally intricate *examples* of the fixed point theorem that has ever been written down.
